# 2D Sketches

2D Sketching is one of the most fundamental parts of Autodesk Inventor, providing the base-line geometry for creating 3D features. They are used everywhere, from extrusion cross-sections to guide rails to surface boundaries.

## Creating a Sketch

2D sketches can be created in any plane or flat surface, via any of the following ways:

- Clicking on a plane or flat surface and selecting "Create Sketch" on the popup ribbon
- Clicking on a plane or flat surface and selecting "3D Model > Sketch > Start 2D Sketch" or "Sketch > Sketch > Start 2D Sketch" on the window ribbon
- Right clicking on a plane or flat surface and selecting "New Sketch" on the popup wheel
- Selecting "3D Model > Sketch > Start 2D Sketch" or "Sketch > Sketch > Start 2D Sketch" on the window ribbon and then clicking on the desired plane or flat surface
- Right clicking on the model browser and selecting "New Sketch"

## Adding Geometry

### Tips and Tricks for Adding Geometry

- You can usually specify the coordinates of key points or the dimensions of your geometry (magnitude and angle). Press "Tab" to specify coordinates or switch between multiple dimensions.
- The bottom right of your workspace will display a lot of useful information when creating geometry, such as coordinate positions, deltas, and dimensions.
- You can "snap" your geometry to existing points. A green dot will signify you are placing your geometry on an existing point, and a yellow dot will signify you are placing your geometry along an existing curve. This is often useful to make sure that all your lines connect to form a closed shape.
- The above is a case of constraint inference (ref. Constraints), and you can align your geometry in other ways, such as drawing a line which is tangent to another curve. You can temporarily disable constraint inference or point snapping by holding CTRL.
- When starting the Line command, you can easily create tangent or normal lines. Click your starting point on existing geometry, and then click and drag the starting point. The direction you drag determines whether the line will be tangential or normal.
- Existing 3D objects can sometimes obstruct your view of your sketch. You can either change the camera angle or Right Click > "Slice Graphics".

## Types of Geometry

When selecting the start point of a line, you can click and drag on existing geometry to create a line which is tangent/perpendicular (see "Constraints"). There are several types of geometry which can be placed:

- **Line:** Creates either simple lines or joined segments of lines and arcs. Click on your starting point, and then your endpoint (to create a line) or click and drag your starting point (to create a curve). Finish the command by double clicking on the final endpoint or click ESC.
- **Spline:** Creates a spline (parametric curve), either by specifying points for the spline to pass through or control vertices.
- **Equation Curve:** Creates a curve based on a mathematical equation. The equation can be explicit or parametric, and use polar or cartesian coordinates.
- **Bridge Curve:** Creates a curve that joins two line/curve endpoints together such that the bridge curve is tangent to both segments (ref. G2 Smooth Constraint).
- **Circle:** Creates a circle, using either a center point or three tangent lines.
- **Ellipse:** Creates an ellipse based on two axial lines
- **Arc:** Creates an arc, using the endpoints and either a center point or midpoint (Three Point Arc). Can also create an arc that joins a line's endpoint and is tangent to it.
- **Rectangle:** Creates a rectangle using various key points.
- **Slot:** Creates a slot or capsule, using various key points.
- **Polygon:** Creates a polygon of any order, and can be drawn inscribed or circumscribed.
- **Fillets and Chamfers:** Transforms sharp corners into curved corners (fillets) or bevelled corners (chamfers). The radius or angle of these fillets/chamfers can be adjusted in the popup dialog.
- **Text:** Creates text as geometry, which can be further extruded, swept, etc. Various formatting options can be adjusted in the popup dialog.
- **Geometry Text:** Creates text that lies along lines or simple curves. Cannot be used for more complex geometries such as splines.
- **Point:** Creates points.

## Projecting Geometry

The Project Geometry feature is a very powerful tool which allows you to copy existing geometry, whether 2D or 3D, to your current sketch. Try to always project geometry which is above the current sketch in the model browser. Generally, projected geometry is adaptive, which means changes to the reference geometry will be reflected in your sketch. To prevent this, hold down CTRL when projecting geometry, right click on the geometry and select "Break Link", or manually delete the Project Geometry Constraint (ref. Constraints). There are the following options:

- **Project Geometry:** Projects 2D sketches, 3D sketches, object edges and more into your sketch.

- **Project Cut Edges:** Projects the cross-section that the sketch plane makes with any object. Can also be used to project the intersection of the sketch plane with a composite feature or surface.
- **Project Flat Pattern:** Used predominately in sheet metal projects, unfolds an object into the plane.
- **Project to 3D Sketch:** Used to project your 2D sketch onto a 3D surface. For more information on this group of features, see "3D Sketches" or "3D Model & Surface".
- **Project DWG Geometry:** —————

## Geometry Patterns

Inventor allows you to duplicate geometries to streamline your work. Geometry can be mirrored or repeated in a circular or rectangular pattern. The patterns are associative, so changes to any one of the object instances will change the entire pattern.

## Modifying Existing Geometry

The Modify tab allows you to make changes to geometry you have already created. You can:

- Move geometry
- Copy geometry to a new location
- Rotate geometry
- Scale geometry
- Trim parts of your geometry off by points of intersection
- Extend a line or other geometry until it intersects with another geometry
- Split geometry into multiple parts according to points of intersection.
- Stretch certain geometry out
- Offset geometry by creating a slightly larger or smaller copy.

### Tips and Tricks

- You can change how Inventor treats dimensions and constraints (i.e if it breaks constraints or throws an error) by clicking the "¿¿" button on the popup dialog of the modify tools and changing the settings.
- By checking the "Precise Input" box on the popup dialog of many of these tools, you can specify the exact coordinates with which you want to modify your geometry with.
- You can choose whether an offset geometry adapts to changes in the original geometry by right clicking when using the Offset tool and toggling "Constrain Offset". Under these options, you can also change whether Inventor offsets entire loops or single line/curve segments.

## Constraints and Dimensions

Constraints and dimensions determine the relationships between geometries. If a sketch is not fully constrained, it means that you can freely move it around by simply clicking and dragging. We recommend that, in general, you fully constrain all sketches. The bottom right of your workspace will tell you how many more dimensions/constraints you would need to achieve this.

### Dimensions

Dimensions allow you to display and specify the length or angle between two pieces of geometry. Dimensions can also be added when creating geometry, by pressing Tab to toggle between possible dimensions. The following dimensions can be created (noting that curves are usually dimensioned by the center point):

1. Two parallel lines: the distance between them
2. Two nonparallel lines: the angle between them
3. Two curves/points: the distance between them. The movement of your cursor dictates whether this will be the vertical distance or horizontal distance. By clicking a third time in between the two points, the dimension will be the Euclidean distance.
4. A line and curve/point: the distance between them in the direction orthogonal to that of the line

Two types of dimensions can be created: regular dimensions and driven dimensions. Driven dimensions are dimensions which are redundant (already specified by existing constraints/dimensions), and thus are only used to display measurements. They are signified by brackets. On the other hand, regular dimensions can be edited to change the geometry. Regular dimensions can be made and unmade driven by selecting "Format > Driven Dimension" or by right clicking and selecting "Driven Dimension".

Dimensions can be edited by double clicking on the dimension. The formatting of the dimension can be modified by right clicking and selecting "Dimension Properties", allowing you to specify naming, precision, and tolerance type for both the individual dimension and the default settings.

### Types of Constraints

1. Coincident: a point is constrained to another point or along another curve
2. Collinear: two straight lines (or axes) constrained to lie along the same line
3. Concentric: two curves, ellipses or circles constrained to the same center point
4. Fixed: locks geometry in place
5. Parallel: two lines constrained to lie parallel
6. Perpendicular: two lines constrained to lie perpendicular
7. Horizontal: a line or pair of points constrained parallel to the x axis
8. Vertical: a line or pair of points constrained parallel to the z axis
9. Tangent: two curves constrained to be tangent to each other

- 
10. Smooth: a splined curve constrained to be tangent to and join endpoints with a curve
  11. Symmetric: two curves constrained to be symmetric about a third selected line
  12. Equal: two curves constrained to have the same radius or two lines constrained to have the same length
  13. Project Geometry: essentially a fixed constraint, it cannot be added to geometry but instead is automatically applied to any projected geometry. If you want to edit projected geometry, you need to remove these constraints.

## Adding Constraints

Constraints can be added through the "Constrain" tab. Select the desired constraint in the tab and then select the geometry to be constrained. For some constraints such as the fixed or equal constraint, you can select multiple geometry and then click on the desired constraint to apply to all.

## Viewing and Editing Constraints

All constraints can be viewed by right clicking on the workspace and selecting "Show All Constraints" or using the F8 hotkey. Constraints can be hidden by right clicking on the workspace and selecting "Hide All Constraints" or using the F9 hotkey.

To toggle the visibility of a selected geometry's constraints, click on the "Show Constraints" icon under the "Constrain" tab in the ribbon.

To delete all constraints from geometry, select the desired geometry, press right click and select "Delete Constraints".

To delete specific constraints, show constraints either by using F8 or selecting the parent geometry, click on the respective constraint icon beside the geometry and press DEL.

## Constraint Inference, Relax Mode and Settings

Sometimes constraints can be inferred while placing geometry. For example, drawing a line which is horizontal will create an inferred horizontal constraint, and likewise for constraints such as parallel constraints. If you find that a constraint is being inferred with the wrong geometry (for example if you want to a parallel constraint to one line but it infers a parallel constraint with another), you can first mouseover ("scrub") the desired constraint geometry. You can temporarily disable inferred constraints by holding CTRL when placing geometry.

Inferred constraints can be persistent or non-persistent. Persistent constraints remain after the geometry is placed, however non-persistent constraints will not, and will only help you while placing geometry.

Usually, constraints will restrict you from freemoving geometry. For example, if you have two circles with a concentric constraint, moving one circle will also cause the other to move. When Relax Mode is enabled, geometry can be moved freely. Instead of also moving constrained geometry, any constraints which are broken will be deleted. In the above case, only the selected circle will move and the concentric constraint will be removed. You can also choose to only enable Relax Mode for specific constraint types.

Settings for constraints can be modified under "Constraint Settings" under the "Constrain" tab. You can:

1. Under "Inference", turn all inferred constraints on/off
2. Under "Inference", turn specific inferred constraints on/off, such as turning off any inferred horizontal constraints
3. Under "Inference", choose to infer parallel/perpendicular constraints over horizontal/vertical constraints, when there is an option
4. Enable "Relax Mode"

## Automatic Dimensions

By selecting "Automatic Dimensions and Constraints" under the "Constrain" tab, dimensions and constraints can be added to fully parameterise the sketch.

## Formatting

The graphic display of geometry can be adjusted under the "Format" tab. Construction formatting identifies geometry as being a scaffold to the sketch and not part of the final product, such as radius lines. These are still visible and can be dimensioned/constrained, however cannot be used for extrusions or any other 3D feature. Some shapes, such as center point rectangles, automatically come with construction lines, and in order to use these lines for 3D features it must be disabled in the same way construction lines are enabled.

Centerline formatting signifies a line being a symmetric center of geometry, and behaves in the same way as construction lines. Center points have the same philosophy.

Geometry can also be custom formatted by changing the pattern, colour and weight. These custom formats can be turned on/off by clicking "Show Format" under the "Format" tab.

## Layout

### Assembly and Component Layouts

This is part of a more complex feature of Inventor which comprises of creating hierarchies of assemblies, components and parts. In short, the Make Part and Make Components features allows you to import 2D sketches into assemblies as layout parts. This is useful because you can create 3D features in the assembly without changing the layout file, and as such these files can be used concurrently for multiple projects.

### Sketch Blocks

Sketch blocks are similar to object grouping in Microsoft Office; it allows you to constrain portions of sketches to be fixed relative to each other, and instead of moving each piece of individual geometry the entire block moves. This is especially useful if you copy and paste a lot of sketch data from other applications or do a lot of sketching over images - it removes the need to constrain every line and curve. Sketch blocks can be created under "Layout > Create Block"

## Insert

### Inserting Images

Images can be inserted into a 2D sketch under "Insert > Image", and behave like construction-formatted rectangles in terms of geometry. Inserting images is a fantastic way to model objects that do not have CAD files, as you can use them to freehand outlines - learn how to create 3D models from just 2D profile images in the "3D Sketch" section!

## Inserting Points Spreadsheets

If you have a large number of points that you want to copy into modelling software - such as from point cloud scanners - your best option is to import it via an excel spreadsheet. Your first row should contain only your units specification, your second row should contain the headings x, y and (optionally) z. Each subsequent row should represent the coordinates of one point.

## Inserting AutoCAD Files

If you use AutoCAD to create drawings, you can import 2D drawings into a sketch here. This should work for any DWG or DXF file.

## Parameters

Ref. Parameters

# 3D Modelling

This is where all the magic happens! Transform sketches into 3D features, surfaces and more.

## Creating Features

In order to create a feature, you need to have valid sketches. The following features can be created:

### Extrude

Takes a 2D cross-section and extrudes it into a prism.

**Surface Mode:** Instead of creating a prism, you can set the extrusion to create a surface instead, by selecting the relevant button on the top right of the popup dialog.

**Profiles:** These are the cross-sections which are to be extruded. Select them by clicking on any desired closed areas within a single sketch.

**From:** Choose the plane that the extrusion will start at (it does not have to be the sketch plane, although it will default to this).

**Direction:** The extrusion can be set as in either direction, symmetric in both directions or asymmetric in the two directions.

**Distance:** The distance of extrusion can be set as:

- **Manual Distance:** specify the numerical distance of extrusion (for asymmetric extrusions you will need to specify a distance for each direction). You can click the arrow beside the input box to quickly measure dimensions, use an existing dimension for reference or use recently used values.
- **Through All:** the extrusion will pass through all objects (also can be used for cut or intersect extrusions).
- **To:** select the plane or feature that the extrusion will end at. If the feature has multiple possible termination points (such as the closest and furthest side of a cylinder), select Alternate Solution to end the extrusion at the closest face of the feature
- **To Next:** the extrusion will end at the next feature or plane. Said feature or plane should entirely overlay the cross-section profile.

**Output:** Determines the output of the extrusion, either:

- **Join:** adds extrusion to the selected solid
- **Cut:** removes material from the selected solid
- **Intersect:** keeps the intersection between the extrusion and the selected solid
- **New Solid:** creates the extrusion as a new solid

**Taper:** The extrusion tapers slightly inwards (negative values) or outwards (positive values).

**Settings:** Additional settings can be accessed by the hamburger menu on the top right of the popup dialog. Of most note is the option to keep the sketch visible after extrusion - otherwise, the sketch will be consumed in the process.

## Revolve

Revolves a section around a specified axis.

**Surface Mode:** Instead of creating a solid feature, you can set the revolution to create a surface instead, by selecting the relevant button on the top right of the popup dialog.

**Profiles:** These are the cross-sections which are to be revolved. Select them by clicking on any desired closed areas within a single sketch.

**From:** Choose the plane that the revolution will start at (it does not have to be the sketch plane, although it will default to this).

**Direction:** The revolution can be set as in either direction, symmetric in both directions or asymmetric in the two directions.

**Distance:** The distance of revolution can be set as:

- **Manual Angle:** specify the numerical angle of revolution (for asymmetric extrusions you will need to specify a distance for each direction). You can click the arrow beside the input box to quickly measure dimensions, use an existing dimension for reference or use recently used values.
- **Full:** a 360 degree revolution
- **To:** select the plane or feature that the extrusion will end at. If the feature has multiple possible termination points (such as the closest and furthest side of a cylinder), select Minimum Solution to end the revolution at the closest face of the feature.
- **To Next:** the extrusion will end at the next feature or plane. Said feature or plane should entirely overlay the cross-section profile.

**Output:** Determines the output of the revolution, either:

- **Join:** adds revolution to the selected solid
- **Cut:** removes material from the selected solid
- **Intersect:** keeps the intersection between the revolution and the selected solid
- **New Solid:** creates the revolution as a new solid

## Sweep

Takes a 2D cross section and sweeps it across a path to create a pipe-like feature.

**Surface Mode:** Instead of creating a solid object, you can set the sweep to create a surface instead, by selecting the relevant button on the top right of the popup dialog.

**Profiles:** These are the cross-sections which are to be swept. Select them by clicking on any desired closed areas within a single sketch. They do not necessarily have to be connected but errors may occur if you try to sweep dispersed profiles along tricky paths. The

**Path:** Choose the path (a 2D/3D curve or edge) for the profiles to follow. It does not necessarily have to intersect the profiles, but the path must intersect the profile plane.

**Behaviour:** Determines how the profile follows the path:

- **Follow Path:** the profile is swept along the path, where every cross section taken normal to the path stays constant. Adjust the twist and taper as necessary - 360 degree twist corresponds to one single twist, and positive/negative taper corresponds to a widening/narrowing of the sweep away from the start point.

- 
- Fixed: the profile is swept along the path, where the cross section taken parallel to profile plane stays constant. Twist and taper are not available.
  - Guide:

Output: Determines the output of the sweep, either:

- Join: adds sweep to the selected solid
- Cut: removes material from the selected solid
- Intersect: keeps the intersection between the sweep and the selected solid
- New Solid: creates the sweep as a new solid

## Primitives

Primitives provide shortcuts to easily create basic features: a box, sphere, cylinder or torus. These features just reuse the Create features detailed above.
